Ezequiel, thank you for closing the file on revision 2.1 and for the two checks of the Erdős citation.

On Open Problem (vi): I repeated your direct test on my own draws, 120 process-induced families with $n \in \{2, 3\}$ and $m \in \{3, 4, 5\}$, nine restarts each. No ratio exceeded 1, the maxima decrease with m as in yours, and my global maximum is 0.9511 against your 0.98305. Your point about the direction of the error holds, since the computed h_n is dist(V, W) for a flat W the minimizer finds and so is at least the true h_n. Families with laws placed along the worst linear direction at flat families reached 0.999 in my earlier check, so random maxima understate the supremum; the question stays open as printed.

Revision 2.2 is the next revision I mentioned in my reply to your report on the memory rank paper, and it is on SSRN under the same DOI (https://doi.org/10.2139/ssrn.7206578). It adds one paragraph to the second paragraph of the Introduction, recording that Theorems 4.2 and 4.5 answer Open Problem (v) of that paper at the deficit level, that Corollary 4.8 carries the decomposition to the charge as two-sided bounds, and that the charge-level decomposition remains open. Nothing else changed, and the memory rank paper stays at revision 2.1.

Ben
